

Class 08: Breast Cancer Mini Project

Melanie Alonzo (PID: A17375327)

Table of contents

Background	1
Data Import	1
Principal Component Analysis (PCA)	5
Communicating PCA results	10
4. Hierarchical Clustering	10
Combining methods	11
Prediction	13

Background

In today's class we will be employing all the R techniques for data analysis that we have learned thus far - including the machine learning methods of clustering and PCA - to analyze real breast cancer biopsy data.

Data Import

The data is in CSV format:

```
fna.data <- "WisconsinCancer.csv"
wisc.df <- read.csv(fna.data, row.names=1)
```

We peek at the data

```
head(wisc.df, 3)
```

	diagnosis	radius_mean	texture_mean	perimeter_mean	area_mean
842302	M	17.99	10.38	122.8	1001
842517	M	20.57	17.77	132.9	1326

Q1. How many observations are in this dataset?

```
nrow(wisc.df)
```

```
[1] 569
```

Q2. How many of the observations have a malignant diagnosis?

```
sum (wisc.df$diagnosis == "M" )
```

```
[1] 212
```

```
table (wisc.df$diagnosis)
```

```

B    M
357 212

```

Q3. How many variables/features in the data are suffixed with `_mean`?

```
head(wisc.df)
```

[31] "fractal_dimension_worst"

```

We need to remove the `diagnosis` column before we do any further analysis of this dataset - we don't want to pass this to PCA etc. We will save it as a separate vector that we can use later to compare our findings to those of experts.

```

wisc.data <- wisc.df[,-1]
diagnosis <- wisc.df$diagnosis

```

Principal Component Analysis (PCA)

The main function in base R is called `prcomp()` we will use the optional argument `scale=TRUE` here as the data columns/ features/ dimensions are on very different scales in the original data set.

```

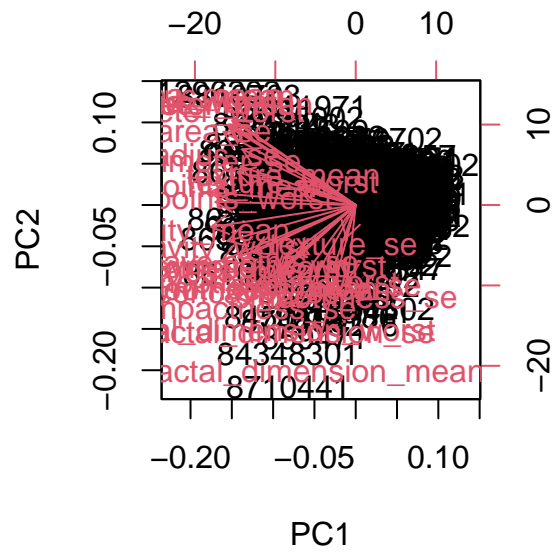

wisc.pr <- prcomp(wisc.data, scale=T)

```

```

biplot(wisc.pr)

```

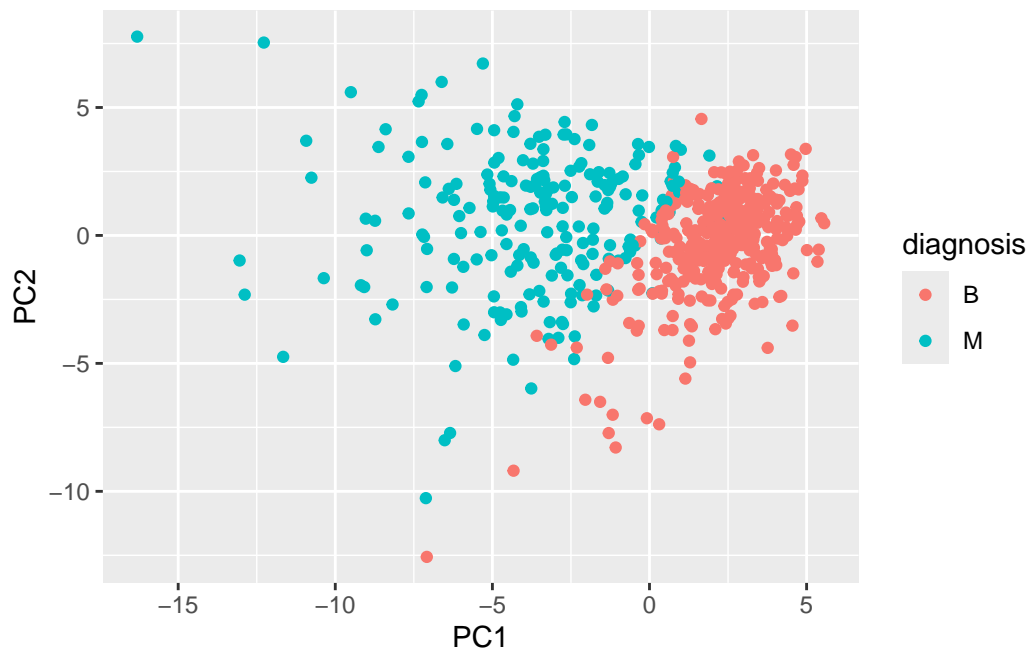

```
attributes(wisc.pr)
```

```
$names
[1] "sdev"      "rotation" "center"    "scale"     "x"

$class
[1] "prcomp"
```

```
library(ggplot2)
ggplot(wisc.pr$x) +
  aes(PC1, PC2, col= diagnosis) +
  geom_point()
```

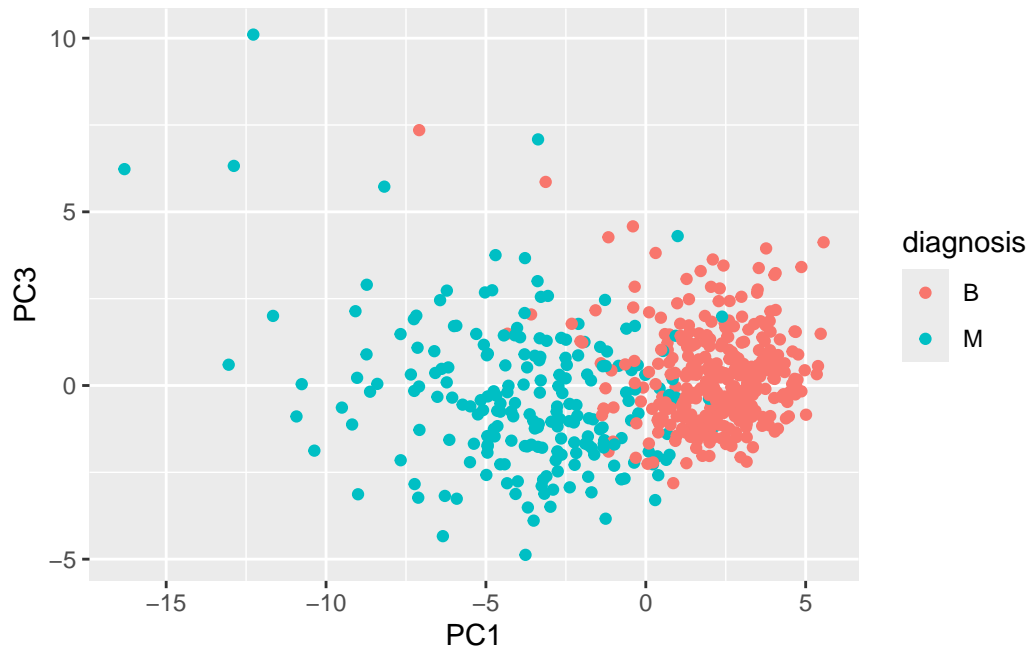

```
summary(wisc.pr)
```

Importance of components:

	PC1	PC2	PC3	PC4	PC5	PC6	PC7

  geom_point()
```

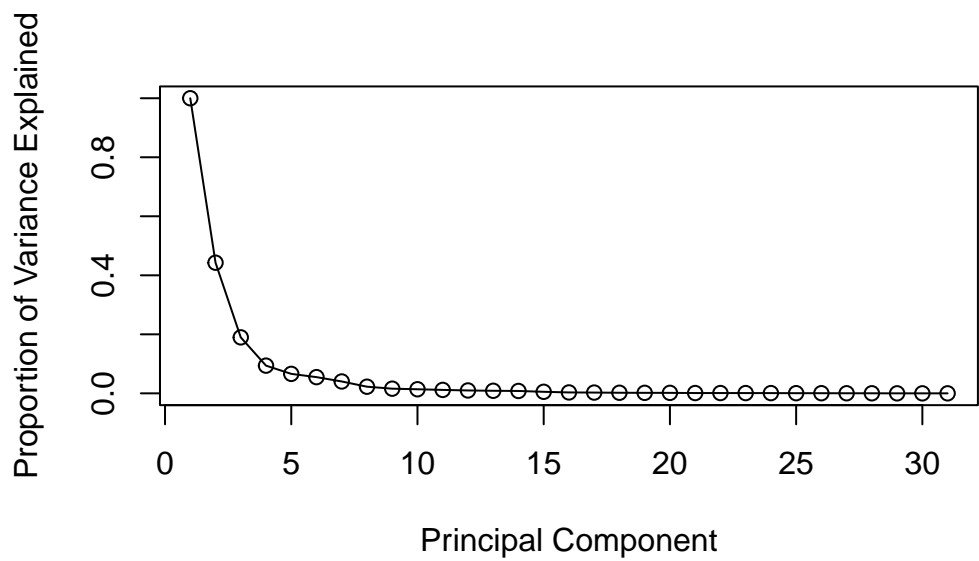

```
pr.var <- wisc.pr$sdev^2
head(pr.var)
```

```
[1] 13.281608  5.691355  2.817949  1.980640  1.648731  1.207357
```

```
pve <- pr.var / sum(pr.var)
```

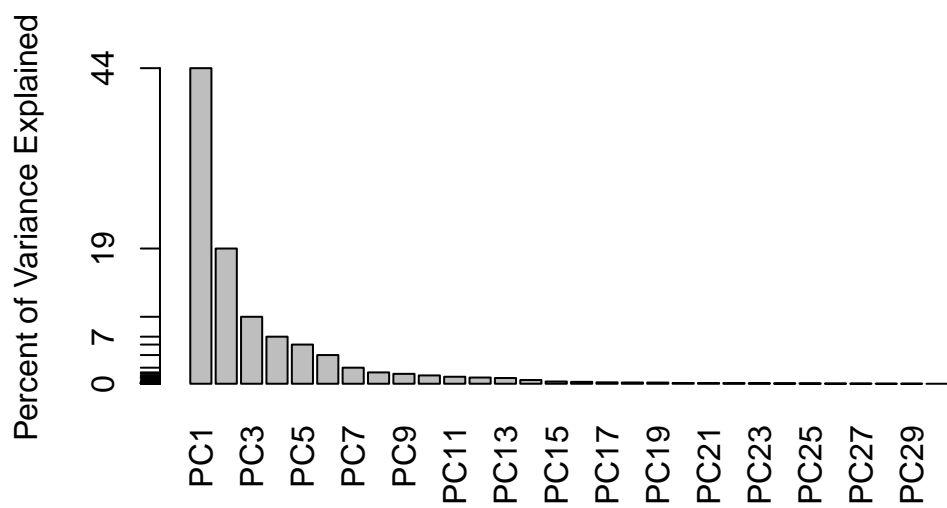

```
plot(c(1,pve), xlab = "Principal Component",
     ylab = "Proportion of Variance Explained",
     ylim = c(0, 1), type = "o")
```

```

barplot(pve, ylab = "Percent of Variance Explained",
        names.arg=paste0("PC",1:length(pve)), las=2, axes = FALSE)
axis(2, at=pve, labels=round(pve,2)*100 )

```

Communicating PCA results

Q9. For the first principal component, what is the component of the loading vector (i.e. `wisc.pr$rotation[,1]`) for the feature `concave.points_mean`? This tells us how much this original feature contributes to the first PC. Are there any features with larger contributions than this one?

```
wisc.pr$rotation ["concave.points_mean", "PC1"]
```

```
[1] -0.2608538
```

4. Hierarchical Clustering

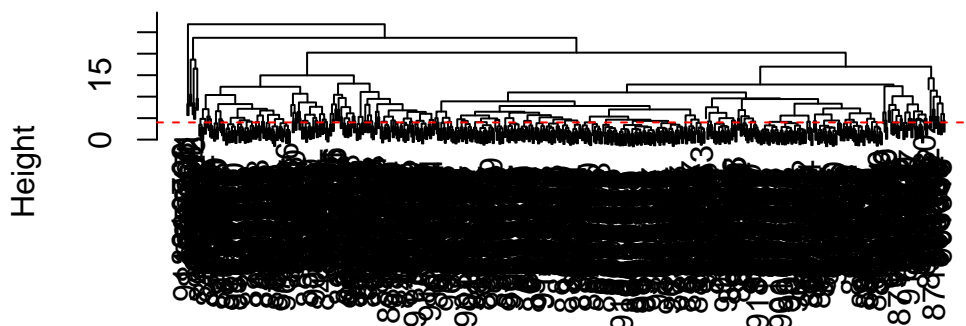

The goal of this section is to do hierarchical clustering of the **original data** to see if there is any obvious grouping into malignant and benign clusters.

In short, these results are not good!

First we will scale our `wisc.data` then calculate a distance matrix, then pass to `hclust()`:

```
wisc.dist <- dist( scale(wisc.data))  
wisc.hclust<- hclust( wisc.dist)  
plot(wisc.hclust)  
abline(h=4, col="red", lty=2)
```

Cluster Dendrogram

```
wisc.dist  
hclust (*, "complete")
```

```
wisc.hclust.clusters <- cutree(wisc.hclust,k=2)  
table(wisc.hclust.clusters)
```

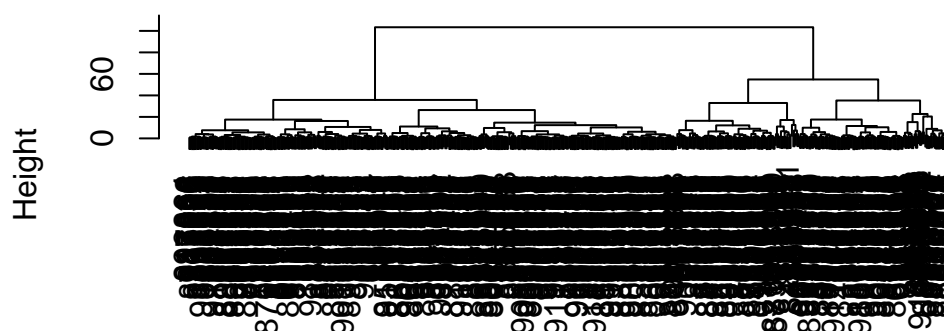

```
wisc.hclust.clusters  
  1  2  
567  2
```

Combining methods

The idea here is that I can take my new variables (i.e. the score on the PCs `wisc.pr$x`) that are better descriptors of the data-set than the original features (i.e. the 30 columns in `wisc.data`) and use these as a basis for clustering.

```
pc.dist <- dist(wisc.pr$x[,1:3])  
wisc.pr.hclust <- hclust(pc.dist, method= "ward.D2")  
plot(wisc.pr.hclust)
```

Cluster Dendrogram

pc.dist
hclust (*, "ward.D2")

```
grps <- cutree(wisc.pr.hclust, k=2)
table(grps)
```

```
grps
  1  2
203 366
```

```
table(diagnosis)
```

```
diagnosis
  B  M
357 212
```

I can now run `table()` with both my clustering `grps` and the expert `diagnosis`

```
table(grps, diagnosis)
```

```
      diagnosis
grps   B    M
  1  24 179
  2 333  33
```

Our cluster “1” has 179 “M” diagnosis or cluster “2” has 333 “B” diagnosis

- 179 TP
- 24 FP
- 333 TN
- 33 FN

Sensitivity: $TP/(TP+FN)$

```
179/(179+33)
```

```
[1] 0.8443396
```

Specificity: $TN/(TN+FP)$

```
333/(333+24)
```

```
[1] 0.9327731
```

Prediction

We can use our PCA model for prediction of new un-seen cases:

```
#url <- "new_samples.csv"
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc
```
